

## Phylum Annelida (segmented worms, bristle worms)

15,000 species

large successful phylum in water & on land

include earthworms, sand worms, bristle worms, clam worms, fan worms, leeches

worldwide distribution:

marine, brackish, freshwater and terrestrial

### **Body Form**

elongated wormlike body

<1mm to 3 meters

hollow **tube-within-a-tube** design

one of the most successful animal designs

→ room for development of complex organs with muscle layers

→ allows for circulation of body fluids

→ provides hydrostatic skeleton

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

1

true **coelom** present

**mesoderm** on inside of body wall and outside of digestive system

layers of muscles inside body wall and on outside of digestive tract

with **head-body-pygidium**

some with bizarre forms

**head** (prostomium & peristomium)

most annelids show some degree of **cephalization** with a distinct head (=prostomium)

**tentacles, palps** and sensory structures

**peristomium** behind prostomium contains the mouth

with **pharynx** and chitinous **jaws**

**body** with well developed **metamerism** (=segmentation)

most prominent distinguishing feature

seen in just a few other phyla: eg arthropods, chordates

segments are separated by tissue = **septae**

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

2

each segment has its own set of muscles and other organs

allows more efficient **hydrostatic skeleton** for burrowing and movement

offers a way to achieve greater size:

rather than increasing size of each organ

→ each organ is repeated in each segment

allows organs of each segment to become more specialized for various functions such as digestion, respiration, reproduction, locomotion, etc

the segmentation is both external and internal

essential features of segmentation:

several systems (eg. nervous, excretory) show serial repetition

segmentation is produced during embryonic development

**NOT** the same as asexual budding as in tapeworms

terminal **pygidium** with anus

### **Body Wall**

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

3

epidermis a single layer of cells (columnar epithelium)

epidermis secretes a thin flexible protective **cuticle**

most annelids have **setae** → small chitinous bristles

secreted by epidermis

repeated on each segment (ie. "bristle worms")

used as anchors while burrowing

to prevent capture

some used for swimming

or as protection or camouflage

beneath **epidermis** is two layers of **muscle tissue**

thin layer of **circular muscle**

thick layer of **longitudinal muscle** (obliquely striated)

enhances use of hydrostatic skeleton

allows for peristaltic movement for digging through sediment

body cavity a true **coelom**

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

4

lined with **peritoneum** (squamous epithelium)

lines inside of body wall & outside of digestive tract

also layers of muscle along digestive tract

peritoneum also form **mesenteries** that hold blood vessels and the **septae** between segments

### **Movement**

coelom is filled with fluid (except leeches) which serves as **hydrostatic skeleton**

annelids have 3 general types of movements:

#### 1. **burrowing**:

waves of **peristaltic contractions** sweep down body

1<sup>st</sup> animal elongates → contraction of circular muscle

2<sup>nd</sup> animal shortens → contraction of longitudinal muscle

**setae** anchor hind end of body while front end pushes forward

#### 2. **crawling**:

polychaetes use parapodia alternately to move

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

5

across surface

#### 3. **swimming**:

mainly polychaetes and leeches

undulating body movements

parapodia help in polychaetes

### **Feeding & Digestion**

complete digestive tract "tube within a tube" design

muscle layers allow modification of tract into various structures:

muscular **pharynx** - to take in food, often with **versible pharynx** with **jaws**

**crop** - food storage

**gizzard** - food grinding

**intestine** - digestion and absorption of nutrients

**anus** - elimination of undigested wastes

### **Respiration**

through body wall in most species

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

6

body wall is richly supplied with capillaries to absorb and transport oxygen

some marine forms respire through **parapodia**

a few species have gills

### **Circulation**

body cavity is filled with coelomic fluid which helps move food and wastes around

most annelids also have a **closed circulatory system** that more efficiently carries nutrients and wastes

several pairs of "pumping hearts" keep blood flowing

**dorsal** and **ventral vessels** connected by capillary network

dorsal vessel sends blood anteriorly

ventral vessel sends blood posteriorly

dorsal vessel is main pump

several pairs of **aortic arches** (= "hearts") help to keep pressure up in ventral vessel

### **blood:**

most with dissolved blood **pigments** to carry

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

7

oxygen:

hemoglobin (Fe) red - most annelids  
hemerythrin (Fe) red  
chlorocruorin (Fe) green

(only 4 blood pigments known in animal kingdom & annelids have 3 of them)

blood also contains amoeboid cells which engulf foreign particles (like our WBC's)

annelids therefore have a double transport system for foods, gasses, wastes

fluid filled coelom

circulatory system with heart & vessels

→ foods, wastes and respiratory gasses are carried both in blood and in coelomic fluid

### **Nervous System**

have both CNS and PNS

CNS: a pair of dorsal **cerebral ganglia** above the pharynx and **ventral nerve cord**

with paired fused ganglia in each segment

PNS: **nerves** branch off fused ganglia to supply body wall and body organs

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

8

### **Senses:**

simple single celled photoreceptors or clusters of cells **ocelli** (= **eyespots**)

a few polychaete **eyes** have cornea, lens, retina  
→ can form images

**statocysts** in some for balance

**nuchal organ** → ciliated pit in head area

also found in some molluscs and a few other invertebrates

may function in chemoreception

**tentacles & palps** → well developed sense of touch

other simple chemoreceptors

free nerve endings → tactile??

### **Endocrine System**

neurosecretory cells in brain and ganglia

secrete **hormones** that regulate:

reproduction

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

9

secondary sex characteristics

regeneration

### **Excretion**

one pair of **nephridia** (=metanephridia) in each segment similar to that in molluscs

(a few polychaetes have protonephridia or both)

### **nephridic tubule:**

**nephrostome** = funnel like opening into previous segment

**coiled ciliated tubule** surrounded by **capillaries**

**bladder** like structure

**nephridipore** = opening to outside

### **function:**

wastes from coelom are drawn in

salts and organic wastes from blood are discharged into duct

useful stuff is selectively reabsorbed

in earthworms and leeches chloagogue cells collect NH4 or urea and deposit in blood or take directly to nephrostome

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

10

some nitrogen wastes are also excreted through body wall

excretory organs also help in salt and water balance

### **Reproduction and Development**

Annelids have both asexual and sexual reproduction

quite variable within the phylum

### **Asexual**

most can bud to some degree

other spontaneously fragment

### **Sexual**

monoecious or dioecious

most annelids are hermaphrodites

larva, if present = **trochophore**

### **Classification of Annelida**

#### **Class: Polychaeta (Bristle Worms)**

mostly marine

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

11

distinct head with eyes and tentacles

segments with parapodia and lots of setae

no clitellum

#### **Class: Clitellata (Earthworms & Leeches)**

##### **subclass: Oligochaeta (Earthworms)**

mainly terrestrial and freshwater

head absent

fewer setae, no parapodia

##### **subclass: Branchiobdellida**

commensal on crayfish

no setae

posterior sucker only

##### **subclass: Hirudinea (Leeches)**

terrestrial, freshwater or marine

no parapodia or setae

fixed # of segments with "false segments" (=annuli)

anterior and posterior suckers

#### **Class: Echiura (Spoon Worms)**

shallow marine burrowing forms

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

12

once considered a separate phylum

## Class: Polychaeta (Sand Worms)

means "many setae"; also called bristle worms

10,000 species; 2/3rds of all Annelid species

sand worms, bristle worms, fan worms, clam worms, etc

largest, most diverse and most primitive class of Annelids

all are aquatic; mostly marine; worldwide distribution

a few found in freshwater

most 2-4" long (5-10 cm); some up to 10' (3 M)

often brightly colored

deposit feeders, filter feeders, predators, scavengers, live in crevasses, old shells, burrows or construct tubes

some have elaborate filtering structures

eg feather duster worms

a few are pelagic → part of the **plankton**

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

13

14

important in marine food chains

### Body Plan

distinct **head** with mouth and sense organs & wormlike **body** or trunk with repeating segments body segments with flaplike **parapodia**

### Head

have distinct **head**

head has retractable **pharynx** with **chitinous jaws** used to capture prey

lots of different kinds of **sense organs**

1. **chemoreceptors** (nuchal glands) on palps and tentacles
2. touch receptors also on **tentacles** for locating food and shelter
3. eyes (simple eyes = ocelli; and more complex eyes)  
some can focus an image = esp predators  
very similar to cephalopod and vertebrate eyes

### Body or Trunk

on each segment are a pair of flaplike **parapodia**, each with many **bristles** (=setae)

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

15

both parapodia and setae are moved by internal **muscle bands**

these parapodia have a variety of functions and create many bizarre shapes:

- crawling or digging in the sediment; use parapodia as legs
- swimming, use parapodia as paddles
- as gills for respiration
- used as anchors while burrowing or to prevent capture
- to create feeding currents inside tubes
- converted into feathery appendages to filter water
- as protection or camouflage
- in some, parapodia modified into fans and mucous bags for feeding or to create water currents

most polychaetes are active swimmers, crawlers or burrowers in the sediment

### Feeding & Digestion

#### **1. predators**

the most active polychaetes are **predators**

eg. **clam worm or sand worm** (*Nereis*)

up to 10" long

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

16

live in mucus tubes in or near low tide; but can also swim  
 males - iridescent bluish-greenish color  
 females - light green with yellow, orange-red mottling  
 most active at night  
 move out onto sand to search for food  
 use their jaws to capture small animals  
 jaws open as pharynx is everted  
 jaws close as pharynx is retracted

**eg. Blood Worms (*Glycera*)**

red worms, all marine, several species  
 found in shallow waters  
 poor swimmers but good burrowers  
 carnivores  
 on their proboscis are 4 hollow jaws that can inject poison into prey  
 eat other worms and organisms in the sediment  
 painful to humans  
 harvested extensively in NE US for bait

**eg. Scale Worms**

very abundant  
 flattened and covered with scales formed by the modified parapodia

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

17

most are small; some up to 19 cm  
 carnivores  
 many are commensals with other marine inverts

**2. filter feeders**

many polychaetes burrow or live in tubes rather than crawling around on the sediment  
 many sedentary polychaetes are **filter feeders**

**eg. Fanworms, tubeworms, featherduster worms)**

secrete many kinds of tubes:  
 firm calcareous tubes  
 glue sand grains together  
 bits of shell cemented together  
 some burrow  
 most have long feathery tentacles that they extend to filter feed  
 resemble colorful flowers when feeding  
 cilia on tentacles move collected particles toward mouth  
 tentacles can be quickly retracted when threatened  
 often develop specialized food gathering structures for filter feeding  
 leads to tagmosis → fusion and reduction of metamerism

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

18

**eg. *Chaetopterus* (parchment worm)**

secretes parchment like tube  
 creates a continuous current through its tube to feed  
 tubeworm must maintain a flow of water to get oxygen and get rid of wastes  
 → uses modified parapodia as paddles  
 can emit strong bioluminescent flashes  
 burrows often shared by commensal crab

**3. detritus feeders**

other polychaetes eat organic detritus in or on the sediment

**Respiration**

usually through **parapodia**

some have paired **gills** on some segments

**eg. Tangleworms (*Cirratulus grandis*)**

on east and west coasts of US  
 yellow to green; 5-6" long  
 front with great mass of long red hairlike filaments used as **gills**

some have no special organ and exchange across **body surface**

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

19

**Excretion**

**protonephridia** and in some **metanephridia** or both  
 1 pair per segment  
 opens into coelomic compartments  
 tubule absorbs any useful materials and concentrates wastes as fluid passes to nephridiopore

**Senses:**

**eyes:** simple eyespots to complex organs  
 esp in free moving (errant) polychaetes  
 in one group can form image: cornea, lens, retina

**nuchal organs:** ciliated sensory pits

**chemoreceptors** used in food gathering  
**statocysts** in burrowers and tube building forms

**Reproduction & Development**

simple reproductive system

have no permanent gonads

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

20

→ gonads appear as temporary swelling of peritoneum at certain seasons  
gametes are shed either

- through genital ducts
- or through nephridiopore
- or through rupture in body wall

some polychaetes live most of the year as sexually immature individuals = **atokes**

after living 1 or 2 years as benthic organisms they become sexually mature and swollen with gametes = **epitokes**

head shrinks, body enlarges, gonads develop and produce egg or sperm

sometimes only part of the body makes the transformation, breaks off and the rest of the worm lives to repeat next season

#### eg. palolo worm

males and females gather by the millions in one spot

at night determined by phases of the moon  
female releases pheromone

pheromone excites male to circle about female

swarms of epitokes appear at start of moon's last quarter in October or November

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

21

→ sea is literally thick with epitokes  
just before sun rises, epitokes burst to release gametes  
anterior portion of worm returns to burrows  
**=synchronous mating**  
→ ensure most eggs are fertilized  
→ predator saturation  
predators have a field day; but too many prey so some are always left to reproduce  
→ atokes safely in their burrows to repeat next year  
a Samoan holiday to feast on epitokes

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

22

## **Ecological Roles of Polychaetes**

eg. detritus food chains

eg. prominent in marine food webs

#### eg. Beard Worms (pogonophorans)

once thought to be a separate phylum, now known to be an unusual kind of polychaete

discovered in 1900; today 150 known species

all are marine; most live in bottom ooze of deep ocean

in many the forepart bears long **tentacles** giving it a bearded appearance

thin, transparent, segmented trunk has several pairs of setae and is enclosed in a chitinous tube

the trunk ends in a small segmented opisthosoma

the best known of the group of beardworms are the **giant tubeworms** found around deep sea **hydrothermal vents**

some up to 6' long,

with a bright **red plume** that extends from the tube

giant tubeworms are part of an entire ecosystem **not based on photosynthesis**

they are the only non-parasitic animals without a digestive tract

no mouth, digestive tract or anus

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

23

they get most of their nutrients from **symbiotic bacteria** living in a large sac (=trophosome) within the trunk of the worm

the worms are bright red due to hemoglobin in their blood

the worm absorbs the hydrogen sulfide and oxygen in the waters near the vents

these bind to the hemoglobin in the worms blood and are delivered to the symbiotic bacteria in the trunk of the worm

the bacteria harvest energy from H<sub>2</sub>S and convert inorganic elements into sugars for the worm

giant tubeworms reproduce by releasing sperm and eggs into the water

the larvae will drift through the deep water until they locate a hydrothermal vent

they will then settle to a rocky perch

the young tubeworms do have a mouth and gut and feed

as the worm matures the mouth and gut degenerate and the area once holding the digestive systems becomes a bacteria-filled sac

tube worms seem to have few predators

although sometimes crab and shrimp will feed on the worm's red plume

#### eg. Bone eating worms (**Oscedax**)

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

24

major decomposers of deep sea whale carcasses

2001 found red fuzz on whale carcasses in deep ocean

1000's of polychaetes with red plumes up to 6 cm long

new genus and species of polychaete

seem to be unique to "whale fall"

worms have no functional mouth or gut

have symbiotic bacteria that digested oil in bones

→ they degrade hydrocarbons

the bacteria live in rootlike structures of worm that extend in and throughout the bone

worm provides oxygen via blood vessels extending into the roots

### **Economic Impacts of Polychaetes**

eg. human food (samoa)

eg. insecticides

eg. Padan – a powerful insecticide produced from a polychaete worm

eg. anticancer drugs

eg. dolastatins from sea hare (*Dolabella auricularia*) has potential anticancer properties

## **Class Clitellata**

new genetic analysis indicates that what used to be 3 separate "classes" of segmented worms should more correctly be subclasses of a "new" class: **Clitellata**

the **clitellum** is part of the reproductive system of these worms

it is near the head

the clitellum is a thick, glandular, non-segmented region in these worms that secretes mucus to hold cross-fertilizing worms together while mating

and it produces a sac in which eggs are placed

### **Subclass Oligochaeta (Earthworms)**

means "few setae"

over 3000 species

relatives of sand worms but:

**no distinct head**

**no parapodia**

and very **few setae**

most with 4 prs of short setae/segment

often present in high densities:

rich soil 1 ton of common earthworms/acre

very small aquatic worms (tubificids) up to 40,000/M<sup>2</sup> in rich muds

earthworms are extremely important in the texture and fertility of the soil

Aristotle referred to them as "the intestines of the earth"

Darwin wondered whether there was any other animal that has played so important part in the history of the world as earthworms

"Earthworms are miniature topsoil factories, they make soil. ALL other (terrestrial) living things eventually pass through an earthworm on the way to becoming soil. And it is likely that nearly every atom in your body (with very few exceptions) has been in an earthworm's stomach before it was part of you."

most oligochaetes are less than a few inches long

some tropical earthworms get up to 3 M long

**eg. giant Gippsland earthworm**

native to Australia;

average 3' long and 1" diameter, can reach 9' long

dark purple head and blue-grey body

live in deep burrow systems in clay soils along stream banks

take 5 years to reach sexual maturity

breed in warmer months; lay cocoons in their burrows

12" worm hatches in a year

a protected species – being killed from tilling the land as area converts land from grazing to farming

**eg. giant Palouse earthworm**

in Idaho

thought extinct but recently rediscovered

up to 3 ft long, lives in burrows 15' deep

spits at predators

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

29

mostly terrestrial → burrow in the soil

most conspicuous 'worms' on land

(roundworms are much more abundant but microscopic)

many species are common in freshwaters

**eg. Aquatic "earthworms"**

smaller, benthic, longer setae, more active

better developed sense organs

some have gills

generally eat algae and detritus

some with great powers of asexual budding

**eg. tubifex**

red worms to 10 cm long

live on bottoms of lakes, ponds and polluted streams

live in very low oxygen concentrations

have large amounts of hemoglobin

keep their heads in tubes while waving bright red tails

in heavily polluted areas banks appear bright red at low water

absorb dissolved nutrients (DOM) across skin

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

30

one unusual group lives on glaciers

**eg. ice worms**

small worms <1" long

only found on surface of glaciers at temperatures below freezing

they die at temperatures of 40° F (5°C) or more

can appear by the 100's

eat algae and pollen

and a few oligochaetes are marine or brackish

**Body Wall**

protective layer of collagenous **cuticle** secreted by **epidermis**

surface of the body is kept moist by

**pores** allowing coelomic fluid to leak out and lubricate outer surface of animal

also has numerous **mucous glands**

**Feeding & Digestion**

most oligochaetes are **scavengers** or **detritus feeders**

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

31

feed on decaying organic matter in the soil

eat as they burrow then let digestive system extract nutrients

**mouth** beneath prostomium

inside the mouth is a powerful **pharynx**

in some aquatic species the pharynx can be everted as in sand worms to suck food in

the digestive tract may include:

**esophagus**

has **calciferous glands** that maintain calcium balance by secreting excess calcium from blood into the digestive tract

(lots of calcium in soil; lots gets absorbed, excess is secreted)

**crop** – for food storage

**gizzard** – for grinding up food into smaller pieces

thick and muscular

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

32

**intestine** for chemical digestion and absorption of nutrients

in some the first part of intestine is used for **digestion**

secretes digestive enzymes

most of intestine is used for **absorption**

on dorsal surface is infolding = **typhlosole**

increases surface area for absorption

on outside surface of intestine are yellowish **chloragogue cells**

→ equivalent to our liver: synthesizes glycogen and fats

→ they also travel through coelom to repair wounds

→ function in excretion: convert amino acids to urea & ammonia

### **Respiration**

no respiratory organs or parapodia like polychaetes

breath through skin, no lungs or gills

extensive system of **capillaries** in epidermis

### **Excretion**

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

33

paired **nephridia** in each body segment

in aquatic forms nephridia release ammonia

in terrestrial forms nephridia release urea (conserves water)

in fw and terrestrial oligochaetes nephridia not only eliminate wastes but also eliminate excess water (osmoregulation)

also, terrestrial worms have **calciferous glands**

worms eat soil; soil has lots of calcium

high levels of calcium in blood

calciferous glands remove excess calcium from blood and deposit it in the intestine for removal

### **Sense Organs**

rather than concentrated in head they are distributed all over body

numerous sensory cells (chemo- and mechano-receptors) on skin

chemoreceptors esp on prostomium

many free nerve endings → probably tactile

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

34

earthworms have no "eyes" but do have numerous photoreceptors in epidermis

### **Earthworm Reproduction**

earthworms are **hermaphrodites**

cross fertilize each other

copulation involves a **double exchange** of sperm cells

mucous secreted from **clitellum** holds pair together with genital pores aligned

can last 2-3 hours

sperm is deposited in seminal receptacle

after copulation worms return to burrows

fertilization and egg laying occur a few days later

each worm secretes a sheath of mucous around **clitellum**

clitellum then secretes nourishment for egg

then envelopes mucous and food in tough chitin-like cocoon

the worm then backs out of the cocoon

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

35

as cocoon slips over the genital openings it receives an egg, then sperm

fertilization occurs in the cocoon

cocoon is deposited in soil

in 2-3 weeks a new worm emerges

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

36

## **Ecological Effects of Earthworms**

### **1. Detritus food chain**

#### **eg. Night Crawler**

burrow within the upper 30 cm of moist soil rich in organic matter

in soft soil earthworms move by peristaltic contractions

setae prevent back sliding

this type of movement only works because segments are separated by septa

mainly active at night

on warm damp nights, forage for leaves and organic debris

up to 54,000 earthworms /acre  
→ turn over 18 tons of soil per year

prefer moist soil but if too much water they will move to surface

→ sometimes in great numbers

→ used to think they "rained" down from the sky

important in keeping soil fertile since they are constantly turning over earth and mixing organic matter into it

if all material ever moved through earthworm gut was piled on surface of earth it would rise 30 miles above sea level (5x's height of Mt Everest)

### **2. Food for birds and other animals**

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

37

## **Human & Economic Impacts of Earthworms**

### **1. Food for Humans**

in some parts of Asia, Africa and Latin America people regularly eat worms

usually because there is not much other food available

a few restaurants in the US offer them as novel food fare

### **2. earthworms improve the productivity of farm soil**

sometimes doubling or tripling crop yields

### **3. Fishing bait**

worms are commonly used for freshwater fishing

nightcrawlers, redworms

### **4. Vermicomposting**

using worms to recycle compost

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

38

## **Subclass Hirudinea (Leeches)**

500 sp

mainly freshwater

a few marine and terrestrial

most 2-6 cm long; some to 20 cm

often brightly colored

many are **carnivores**; some are **parasites**

body is dorsoventrally flattened

**anterior** and **posterior suckers**

fixed number of true segments

→ usually 32 plus prostomium & pygidium

each segment with 2-14 **annuli** (=false segments)

### **Body Wall**

coelom functions as a single large chamber

→ no septae between segments

**coelom** is filled with connective tissue and muscle

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

39

except for a system of spaces (=coelomic sinuses and channels) filled with coelomic fluid

→ acts as secondary circulatory system

### **Movement**

**no parapodia**  
(except 1 genus)

**no setae**

leeches have poor hydrostatic skeleton

aquatic species use muscle layers to make undulating swimming movements

can also use suckers to move like inchworms

some terrestrial forms are able to "stand up" on hind sucker to search for prey

### **Feeding & Digestion**

most are **predators** of snails, worms and insect larvae

protrusible **pharynx** with 3 jaws armed with teeth

some are scavengers

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

40

some are blood sucking parasites

#### **adaptations to parasitism** by leeches:

attach to host with suckers

pierce skin with sharp teeth on end of proboscis

while cutting, secrete local anesthetic and histamine-like chemical that dilates blood vessels of host

consume large blood meals

→ blood is sucked by muscular pharynx

while being swallowed, blood mixes with **hirudin** (anticoagulant) to prevent clotting

very slow digestion

gut secretes very few digestive enzymes

→ depend on **bacterial digestion**

can live for almost a year on one meal

may take up to 200 days to digest one meal

can live for another 100 days afterwards

#### **Respiration**

most exchange gasses through skin

a few aquatic forms have **gills**

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

41

#### **Circulation**

many species have no blood vessels

coelomic fluid does the work of blood in open haemocoel

may be hemoglobin in haemocoel fluid

#### **Nervous System**

nervous system similar to other annelids

but leeches have two "brains"

→ one composed of paired cerebral ganglia around pharynx as in other annelids

→ the other in posterior of animal consists of 7 pairs of fused ganglia

simple sense organs are much better developed in terrestrial species which tend to be blood suckers

#### **Reproduction**

hermaphroditic

mating process similar to earthworms

→ cross fertilize during copulation

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

42

do have **clitellum**

→ produce cocoon that receives eggs and sperm

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

43

#### **Human Impacts of Leeches**

##### **1. medicinal uses**

in past centuries medicinal leech, *Hirudo*, was used to suck out "bad blood"

believed many bodily disorders were the result of bad blood or too much blood

→ were collected almost to extinction in Europe

now a protected species

introduced into US but rare in nature

**today** leeches used in medicine to speed healing of reattached fingers and limbs

##### **2. commonly used in biology labs**

3. leeches have become leading **research models** for understanding how the nervous system works

4. some chemicals used by the leech in obtaining and digesting blood are being studied for treating circulatory diseases

5. leeches have also affected history:

**eg. land leeches of India**

live in extremely large numbers in humid forests of India

Animals: Phylum Annelida; Ziser Lecture Notes, 2015.10

44

live in trees and shrubs and fall like "drops of dew" onto any humans passing underneath

their mass attack caused the retreat of a British regiment during the Sikh rebellion in India in mid 1857 (rebellion against East India Company)

## Class: Echiura (Spoon Worms)

140 species

sausage shaped worms

1 cm to 50 cm

all marine

most live in shallow waters; a few deep water forms

→ many burrow in sand or mud

→ other live in rock and coral crevices

→ a few live inside dead sand dollars, mollusc shells, or annelid tubes

they enter shells when young and get too large to leave

generally are deposit feeders

### **Body Form**

cylindrical and somewhat sausage shaped

resemble sipunculans in size and general habits

body in two parts:

anterior flattened **proboscis** (=prostomium)

can be extended and retracted

posterior cylindrical **trunk**

### **Proboscis**

has ciliated groove giving it a spoon-like appearance

proboscis is very mobile

sweeps on mud to find organic debris

can extend up to 10 times its retracted length

eg. *Bonellia* is 7 cm (~3.5") long and can extend its proboscis 1.5 meters (4.5')

no tentacles

### **Trunk**

trunk is gray, reddish brown, or rose

body has several sets of **setae**

→ hooked, anterior setae used for digging burrows

→ setae at posterior end for anchorage

→ circles of setae around posterior end for anchorage and burrow maintenance

### **Feeding and Digestion**

most are deposit feeders

collect small particles of detritus

digestive system is extremely long and coiled

mouth is at base of prostomium

anus is at posterior end of trunk

### **Circulation**

simple closed circulatory system

### **Excretion**

excretion by nephridia

### **Nervous System**

simple nervous system

circumenteric nerve ring

ventral nerve cord

## **Reproduction & Development**

dioecious

show sexual dimorphism;

males often much smaller

gametes shed into water

external fertilization

produces **trochophore** larva

metamorphosis to wormlike adult

some males are parasitic

in some species (eg green spoon worm; *Bonellia viridis*) the first larvae to settle and metamorphose become females

larvae that land on top of female become males

the tiny male creeps up her body, into her mouth and migrates down to her uterus

up to 20 males become parasitic in the females uterus giving her an instant supply of sperm without having to search and mate.

## **Human Impacts**

in arctic spoon worms were once eaten by eskimos
